

7th FL., SHUWA KIOICHO PARK
KYOTO, JAPAN, hereby declare
that the English of Japanese and English
attached pages contains a correct
English of the application document of
Patent Application No. 9-30887 filed on February 14,
2002, in the name of CANON KABUSHIKI KAISHA.

I further declare that all statements made herein of my
own knowledge are true and that all statements made on
information and belief are believed to be true; and further
that these statements were made with the knowledge that
willful false statements and the like so made, are punishable
by fine or imprisonment, or both, under Section 1001 of Title
18 of the United States Code and that such willful false
statements may jeopardize the validity of the application or
any patent issuing thereon.

Signed this 18th day of June, 2002

Yukimitsu EIKAWA

[Title of the Invention]

WAFER PROCESSING APPARATUS AND METHOD, WAFER CONVEY

5 ROBOT, SEMICONDUCTOR SUBSTRATE FABRICATION METHOD, AND
SEMICONDUCTOR FABRICATION APPARATUS

[What Is Claimed Is:]

[Claim 1] A wafer processing apparatus for processing a
wafer by dipping the wafer into a processing solution,
10 characterized by comprising:

a wafer processing bath;

a holding portion for directly or indirectly
holding the wafer; and

a driving portion for supporting said holding
15 portion from above said processing bath to swing said
holding portion within said processing bath.

[claim 2] The apparatus according to claim 1,
characterized in that said driving portion also serves
as a convey mechanism for conveying the wafer between
20 the apparatus and another apparatus.

[claim 3] The apparatus according to claim 1 or claim 2,
further comprising ultrasonic generating means for
generating ultrasonic waves in said processing bath.

[claim 4] The apparatus according to any one of claim 1
25 to claim 3, characterized by further comprising a swing
support member that comes into contact with a peripheral

portion of the wafer in swinging the wafer by said driving portion, thereby supporting swinging by said driving portion.

[claim 5] The apparatus according to claim 4,
5 characterized in that a portion of said swing support member which may come into contact with the peripheral portion of the wafer is rounded.

[claim 6] The apparatus according to claim 4,
characterized in that a portion of said swing support
10 member which may come into contact with the peripheral portion of the wafer has a groove in a direction substantially parallel to a wafer surface.

[claim 7] The apparatus according to claim 6,
characterized in that the groove has a V shape.

15 [claim 8] The apparatus according to claim 6,
characterized in that the groove has a rectified full-wave shape.

[claim 9] The apparatus according to claim 1,
characterized in that said processing bath comprises a
20 circulating mechanism including an overflow bath.

[claim 10] The apparatus according to claim 4,
characterized in that said driving portion swings said holding portion to rotate the wafer when the peripheral portion of the wafer comes into contact with said swing
25 support member.

[claim 11] The apparatus according to claim 3,

characterized in that said ultrasonic generating means comprises an ultrasonic bath, an ultrasonic source, and an adjusting mechanism for adjusting a position of said ultrasonic source in said ultrasonic bath, and

5 ultrasonic waves are transmitted to said processing bath via an ultrasonic transmitting medium placed in said ultrasonic bath.

[claim 12] The apparatus according to claim 1, characterized in that said driving portion comprises a
10 first driving portion for horizontally driving said holding portion, and a second driving portion for vertically driving said holding portion.

[claim 13] The apparatus according to claim 1, characterized in that said holding portion holds the
15 wafer substantially perpendicular to a bottom surface of said processing bath, and said driving portion swings the wafer within a plane substantially perpendicular to the bottom surface of said processing bath.

[claim 14] The apparatus according to claim 1,
20 characterized in that said driving portion swings said holding portion within said processing bath to substantially uniformly process the wafer with a processing solution.

[claim 15] The apparatus according to claim 1,
25 characterized in that said holding portion can hold a wafer holder capable of storing a plurality of wafers.

[claim 16] The apparatus according to claim 1,
characterized in that at least portions of said
processing bath, said holding portion, and said driving
portion, which may come into contact with a processing
5 solution, are made of a material selected from the group
consisting of quartz and plastic.

[claim 17] The apparatus according to claim 1,
characterized in that at least portions of said
processing bath, said holding portion, and said driving
10 portion, which may come into contact with a processing
solution, are made of a material selected from the group
consisting of a fluorine resin, vinyl chloride,
polyethylene, polypropylene, polybutyleneterephthalate
(PBT), and polyetheretherketone (PEEK).

15 [claim 18] A wafer convey apparatus for conveying a wafer,
characterized by comprising:

a holding portion for directly or indirectly
holding the wafer; and

a driving portion for driving said holding portion
20 along a convey path,

said driving portion dipping the wafer into a wafer
processing bath and swinging the wafer midway along the
convey path.

[claim 19] The apparatus according to claim 18,
25 characterized in that said driving portion comprises a
first driving portion for horizontally driving said

holding portion, and a second driving portion for vertically driving said holding portion.

[claim 20] The apparatus according to claim 18, characterized in that said holding portion holds the
5 wafer substantially perpendicular to a bottom surface of said processing bath, and said driving portion swings the wafer within a plane substantially perpendicular to the bottom surface of said processing bath.

[claim 21] The apparatus according to claim 18,
10 characterized in that said driving portion swings said holding portion within said processing bath to substantially uniformly process the wafer with a processing solution in said processing bath.

[claim 22] The apparatus according to claim 18,
15 characterized in that said driving portion swings said holding portion within said processing bath to enhance swinging of the wafer when a peripheral portion of the wafer comes into contact with a projection formed in said processing bath.

[claim 23] The apparatus according to claim 18,
20 characterized in that said driving portion swings said holding portion within said processing bath to rotate the wafer when a peripheral portion of the wafer comes into contact with a projection formed in said processing
25 bath.

[claim 24] The apparatus according to claim 18,

characterized in that said holding portion can hold a wafer holder capable of storing a plurality of wafers.

[claim 25] A semiconductor fabrication apparatus characterized by comprising the apparatus according any
5 one of claim 18 to claim 24, and one or a plurality of wafer processing apparatuses.

[claim 26] A wafer processing method of processing a wafer by dipping the wafer into a processing solution, characterized by comprising dipping a wafer into the
10 processing solution while supporting the wafer from above a wafer processing bath, and swinging the wafer within said processing bath.

[claim 27] The method according to claim 26, characterized in that, while the wafer is swung within
15 said processing bath, ultrasonic waves are generated in the processing solution.

[claim 28] The method according to claim 26 or claim 27, characterized in that, when the wafer is swung within said processing bath, a peripheral portion of the wafer
20 is brought into contact with a projection formed in said processing bath to enhance swinging of the wafer.

[claim 29] The method according to claim 26 or claim 27, characterized in that, when the wafer is swung within said processing bath, a peripheral portion of the wafer
25 is brought into contact with a projection formed in said processing bath to rotate the wafer.

[claim 30] The method according to any one of claim 26 to claim 29, characterized in that the wafer is swung to substantially uniformly process the wafer with the processing solution.

5 [claim 31] The method according to any one of claim 26 to claim 30, characterized in that the wafer is etched by using an etching solution as the processing solution.

[claim 32] The method according to any one of claim 26 to claim 30, characterized in that a wafer having a porous
10 silicon layer is etched by using an etching solution as the processing solution.

[claim 33] A semiconductor substrate fabrication method characterized by comprising fabricating a semiconductor substrate by using the method according to claim 32 in a
15 part of fabrication steps.

[claim 34] A wafer processing method characterized by comprising processing a wafer by using the apparatus according to any one of claim 1 to claim 17.

[claim 35] A wafer processing method characterized by
20 comprising etching a specific layer formed on a wafer by using the apparatus according to any one of claim 1 to claim 17.

[claim 36] A semiconductor substrate fabrication method characterized by comprising fabricating a semiconductor
25 substrate by using the method according to claim 35 in a part of fabrication steps.

[claim 37] A wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising:

completely dipping the wafer into a processing
5 solution, and processing the wafer while changing a strength of ultrasonic waves which act on the wafer.

[claim 38] A wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising:

10 completely dipping the wafer into a processing solution, and processing the wafer while moving the wafer.

[claim 39] A wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by
15 comprising:

completely dipping the wafer in a processing solution, and processing the wafer while swinging the wafer.

[claim 40] A wafer processing method of processing a
20 wafer while supplying ultrasonic waves, characterized by comprising:

completely dipping the wafer in a processing solution, and processing the wafer while swinging the wafer to cross a plane of vibration of ultrasonic waves.

25 [claim 41] A wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by

comprising:

completely dipping the wafer in a processing
solution, supporting the wafer substantially
perpendicular to a plane of vibration of ultrasonic
5 waves, and processing the wafer while swinging the wafer
to cross the plane of vibration of ultrasonic waves.

[claim 42] A wafer processing method of processing a
wafer while supplying ultrasonic waves, characterized by
comprising:

10 completely dipping the wafer in a processing
solution, supporting the wafer substantially parallel to
a plane of vibration of ultrasonic waves, and processing
the wafer while swinging the wafer to cross the plane of
vibration of ultrasonic waves.

15 [claim 43] A semiconductor substrate fabrication method
characterized by comprising:

the step of forming an unporous layer on a porous
layer formed on a surface of a first substrate;

the step of adhering a first substrate side of a
20 prospective structure and a second substrate prepared
separately to sandwich said unporous layer between the
first substrate side and said second substrate;

the removal step of removing said first substrate
from the adhered structure to expose said porous layer
25 on a second substrate side thereof; and

the etching step of etching said porous layer while

the second substrate side on which said porous layer is exposed is completely dipped into an etching solution, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side,

5 the etching step changing a strength of ultrasonic waves which act on the second substrate side.

[claim 44] A semiconductor substrate fabrication method characterized by comprising:

 the step of forming an unporous layer on a porous
10 layer formed on a surface of a first substrate;

 the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich said unporous layer between the first substrate side and said second substrate;

15 the removal step of removing said first substrate from the adhered structure to expose said porous layer on a second substrate side thereof; and

 the etching step of etching said porous layer while the second substrate side on which said porous layer is
20 exposed is completely dipped into an etching solution, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side,

 the etching step moving the second substrate side.

[claim 45] A semiconductor substrate fabrication method
25 characterized by comprising:

 the step of forming an unporous layer on a porous

layer formed on a surface of a first substrate;

the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich said unporous layer between the
5 first substrate side and said second substrate;

the removal step of removing said first substrate from the adhered structure to expose said porous layer on a second substrate side thereof; and

the etching step of etching said porous layer while
10 the second substrate side on which said porous layer is exposed is completely dipped into an etching solution, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side,

the etching step swinging the second substrate side.

15 [claim 46] A semiconductor substrate fabrication method characterized by comprising:

the step of forming an unporous layer on a porous layer formed on a surface of a first substrate;

the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich said unporous layer between the
20 first substrate side and said second substrate;

the removal step of removing said first substrate from the adhered structure to expose said porous layer
25 on a second substrate side thereof; and

the etching step of etching said porous layer while

the second substrate side on which said porous layer is exposed is completely dipped into an etching solution, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side,

5 the etching step swinging the second substrate side to cross a plane of vibration of ultrasonic waves.

[claim 47] A semiconductor substrate fabrication method characterized by comprising:

 the step of forming an unporous layer on a porous
10 layer formed on a surface of a first substrate;

 the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich said unporous layer between the first substrate side and said second substrate;

15 the removal step of removing said first substrate from the adhered structure to expose said porous layer on a second substrate side thereof; and

 the etching step of etching said porous layer while the second substrate side on which said porous layer is
20 exposed is completely dipped into an etching solution and supported substantially perpendicular to a plane of vibration of ultrasonic waves, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side,

25 the etching step swinging the second substrate side to cross the plane of vibration of ultrasonic waves.

[claim 48] A semiconductor substrate fabrication method characterized by comprising:

the step of forming an unporous layer on a porous layer formed on a surface of a first substrate;

5 the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich said unporous layer between the first substrate side and said second substrate;

the removal step of removing said first substrate
10 from the adhered structure to expose said porous layer on a second substrate side thereof; and

the etching step of etching said porous layer while the second substrate side on which said porous layer is exposed is completely dipped into an etching solution
15 and supported substantially parallel to a plane of vibration of ultrasonic waves, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side,

the etching step swinging the second substrate side
20 to cross the plane of vibration of ultrasonic waves.

[Detailed Description of the Invention]

[0001]

[Technical Field to Which the Invention Belongs]

The present invention relates to a wafer processing
25 apparatus and method, a wafer convey robot, a semiconductor substrate fabrication method, and a

semiconductor fabrication apparatus and, more particularly, to a wafer processing apparatus and method which process a wafer by dipping the wafer into a processing solution, a wafer convey robot suitable for this processing, and a semiconductor substrate fabrication method and semiconductor fabrication apparatus to which the processing is applied.

[0002]

[Prior Art]

10 Wet etching is a typical example of processing performed by dipping a wafer into a solution. One subject of wet etching is to improve the in-plane uniformity. Conventionally, the in-plane uniformity is ensured by supplying fresh etching solution to the reaction surface by circulating the etching solution in a bath.

[0003]

Another example of the processing performed by dipping a wafer into a solution is wafer cleaning processing. Japanese Patent Laid-Open No. 8-293478 has disclosed a wafer cleaning apparatus which increases the wafer cleaning efficiency by applying ultrasonic waves while dipping part of a wafer into a solution and rotating the wafer.

25 [0004]

[Problems That the Invention Is to Solve]

The wafer cleaning apparatus disclosed in Japanese Patent Laid-Open No. 8-293478 rotates a wafer upon bringing the wafer into contact with a rotating cam, which makes the cam and its accessories generate
5 particles.

[0005]

In this wafer cleaning apparatus, the strength of standing waves of ultrasonic waves changes at the center and peripheral portion of the wafer. Since the cam
10 obstructs the transmission of ultrasonic waves, the ultrasonic waves cannot be uniformly supplied to the entire surface of the wafer. Accordingly, the wafer cannot be uniformly processed.

[0006]

15 In the wafer cleaning apparatus, ultrasonic waves vibrate the cam and the solution in the bath, and as a result, the wafer also vibrates. The wafer and the cam tend to slip with respect to each other, and the wafer cannot rotate uniformly.

20 [0007]

In the wafer cleaning apparatus, when a wafer having an orientation flat is to be processed, the conditions for transmitting the rotating force from the cam to the wafer change at the orientation flat and the
25 remaining portion. For this reason, the wafer cannot rotate uniformly.

[0008]

The present invention has been made in consideration of the above problems and has as its object to make wafer processing uniform.

5 [0009]

It is another object of the present invention to prevent contamination of a wafer caused by particles.

[0010]

[Means of Solving the Problems]

10 A wafer processing apparatus according to the present invention is a wafer processing apparatus for processing a wafer by dipping the wafer into a processing solution, characterized by comprising a wafer processing bath, a holding portion for directly or
15 indirectly holding the wafer, and a driving portion for supporting the holding portion from above the processing bath to swing the holding portion within the processing bath.

[0011]

20 In the wafer processing apparatus, the driving portion preferably also serves as a convey mechanism for conveying the wafer between the apparatus and another apparatus.

[0012]

25 The wafer processing apparatus preferably further comprises ultrasonic generating means for generating

ultrasonic waves in the processing bath.

[0013]

The wafer processing apparatus preferably further comprises a swing support member that comes into contact
5 with a peripheral portion of the wafer in swinging the wafer by the driving portion, thereby supporting swinging by the driving portion.

[0014]

In the wafer processing apparatus, a portion of the
10 swing support member which may come into contact with the peripheral portion of the wafer is preferably rounded.

[0015]

In the wafer processing apparatus, a portion of the
15 swing support member which may come into contact with the peripheral portion of the wafer preferably has a groove in a direction substantially parallel to a wafer surface.

[0016]

20 In the wafer processing apparatus, the groove preferably has a V shape.

[0017]

In the wafer processing apparatus, the groove preferably has a full-wave rectifying shape.

25 [0018]

In the wafer processing apparatus, the processing

bath preferably comprises a circulating mechanism including an overflow bath.

[0019]

In the wafer processing apparatus, the driving
5 portion preferably swings the holding portion to rotate the wafer when the peripheral portion of the wafer comes into contact with the swing support member.

[0020]

In the wafer processing apparatus, the ultrasonic
10 generating means preferably comprises an ultrasonic bath, an ultrasonic source, and an adjusting mechanism for adjusting a position of the ultrasonic source in the ultrasonic bath, and ultrasonic waves are preferably transmitted to the processing bath via an ultrasonic
15 transmitting medium placed in the ultrasonic bath.

[0021]

In the wafer processing apparatus, the driving
portion preferably comprises a first driving portion for horizontally driving the holding portion, and a second
20 driving portion for vertically driving the holding portion.

[0022]

In the wafer processing apparatus, the holding
portion preferably holds the wafer substantially
25 perpendicular to a bottom surface of the processing bath, and the driving portion preferably swings the wafer

within a plane substantially perpendicular to the bottom surface of the processing bath.

[0023]

In the wafer processing apparatus, the driving
5 portion preferably swings the holding portion within the processing bath to substantially uniformly process the wafer with a processing solution.

[0024]

In the wafer processing apparatus, the holding
10 portion can preferably hold a wafer holder capable of storing a plurality of wafers.

[0025]

In the wafer processing apparatus, at least
portions of the processing bath, the holding portion,
15 and the driving portion, which may come into contact with a processing solution, are preferably made of a material selected from the group consisting of quartz and plastic.

[0026]

20 In the wafer processing apparatus, at least portions of the processing bath, the holding portion, and the driving portion, which may come into contact with a processing solution, are preferably made of a material selected from the group consisting of a
25 fluorine resin, vinyl chloride, polyethylene, polypropylene, polybutyleneterephthalate (PBT), and

polyetheretherketone (PEEK).

[0027]

A wafer convey apparatus according to the present invention is a wafer convey apparatus for conveying a
5 wafer, characterized by comprising a holding portion for directly or indirectly holding the wafer, and a driving portion for driving the holding portion along a convey path, the driving portion dipping the wafer into a wafer processing bath and swinging the wafer midway along the
10 convey path.

[0028]

In the wafer convey apparatus, the driving portion preferably comprises a first driving portion for horizontally driving the holding portion, and a second
15 driving portion for vertically driving the holding portion.

[0029]

In the wafer convey apparatus, the holding portion preferably holds the wafer substantially perpendicular
20 to a bottom surface of the processing bath, and the driving portion preferably swings the wafer within a plane substantially perpendicular to the bottom surface of the processing bath.

[0030]

25 In the wafer convey apparatus, the driving portion preferably swings the holding portion within the

processing bath to substantially uniformly process the wafer with a processing solution in the processing bath.

[0031]

5 In the wafer convey apparatus, the driving portion preferably swings the holding portion within the processing bath to enhance swinging of the wafer when a peripheral portion of the wafer comes into contact with a projection formed in the processing bath.

[0032]

10 In the wafer convey apparatus, the driving portion preferably swings the holding portion within the processing bath to rotate the wafer when a peripheral portion of the wafer comes into contact with a projection formed in the processing bath.

15 [0033]

In the wafer convey apparatus, the holding portion can preferably hold a wafer holder capable of storing a plurality of wafers.

[0034]

20 A semiconductor fabrication apparatus according to the present invention is characterized by comprising the wafer convey apparatus, and one or a plurality of wafer processing apparatuses.

[0035]

25 A wafer processing method according to the present invention is a wafer processing method of processing a

wafer by dipping the wafer into a processing solution,
characterized by comprising dipping a wafer into the
processing solution while supporting the wafer from
above a wafer processing bath, and swinging the wafer
5 within the processing bath. In the wafer processing
method, while the wafer is swung within the processing
bath, ultrasonic waves are preferably generated in the
processing solution.

[0036]

10 In the wafer processing method, when the wafer is
swung within the processing bath, a peripheral portion
of the wafer is preferably brought into contact with a
projection formed in the processing bath to enhance
swinging of the wafer.

15 [0037]

In the wafer processing method, when the wafer is
swung within the processing bath, a peripheral portion
of the wafer is preferably brought into contact with a
projection formed in the processing bath to rotate the
20 wafer.

[0038]

In the wafer processing method, the wafer is
preferably swung to substantially uniformly process the
wafer with the processing solution.

25 [0039]

The wafer processing method is suitable for etching

the wafer by using an etching solution as the processing solution.

[0040]

The wafer processing method is suitable for etching
5 a wafer having a porous silicon layer by using an etching solution as the processing solution.

[0041]

An SOI wafer fabrication method according to the present invention is characterized by comprising
10 fabricating an SOI wafer by using the wafer processing method in a part of fabrication steps.

[0042]

A wafer processing method according to the present invention is characterized by comprising processing a
15 wafer by using the wafer processing apparatus.

[0043]

A wafer processing method according to the present invention is characterized by comprising etching a specific layer formed on a wafer by using the wafer
20 processing apparatus.

[0044]

An SOI wafer fabrication method according to the present invention is characterized by comprising
fabricating an SOI wafer by using the wafer processing
25 method in a part of fabrication steps.

[0045]

A wafer processing method according to the present invention is a wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising completely dipping the wafer into a
5 processing solution, and processing the wafer while changing a strength of ultrasonic waves which act on the wafer.

[0046]

A wafer processing method according to the present
10 invention is a wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising completely dipping the wafer into a processing solution, and processing the wafer while moving the wafer.

15 [0047]

A wafer processing method according to the present invention is a wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising completely dipping the wafer in a processing
20 solution, and processing the wafer while swinging the wafer.

[0048]

A wafer processing method according to the present invention is a wafer processing method of processing a
25 wafer while supplying ultrasonic waves, characterized by comprising completely dipping the wafer in a processing

solution, and processing the wafer while swinging the wafer to cross a plane of vibration of ultrasonic waves.

[0049]

A wafer processing method according to the present invention is a wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising completely dipping the wafer in a processing solution, supporting the wafer substantially perpendicular to a plane of vibration of ultrasonic waves, and processing the wafer while swinging the wafer to cross the plane of vibration of ultrasonic waves.

[0050]

A wafer processing method according to the present invention is a wafer processing method of processing a wafer while supplying ultrasonic waves, characterized by comprising completely dipping the wafer in a processing solution, supporting the wafer substantially parallel to a plane of vibration of ultrasonic waves, and processing the wafer while swinging the wafer to cross the plane of vibration of ultrasonic waves.

[0051]

A semiconductor substrate fabrication method according to the present invention is characterized by comprising the step of forming an unporous layer on a porous layer formed on a surface of a first substrate, the step of adhering a first substrate side of a

prospective structure and a second substrate prepared separately to sandwich the unporous layer between the first substrate side and the second substrate, the removal step of removing the first substrate from the adhered structure to expose the porous layer on a second substrate side thereof, and the etching step of etching the porous layer while the second substrate side on which the porous layer is exposed is completely dipped into an etching solution, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side, the etching step changing a strength of ultrasonic waves which act on the second substrate side. [0052]

A semiconductor substrate fabrication method according to the present invention is characterized by comprising the step of forming an unporous layer on a porous layer formed on a surface of a first substrate, the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich the unporous layer between the first substrate side of a prospective structure and the second substrate, the removal step of removing the first substrate from the adhered structure to expose the porous layer on a second substrate side thereof, and the etching step of etching the porous layer while the second substrate side on which the porous layer is

exposed is completely dipped into an etching solution, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side, the etching step moving the second substrate side.

5 [0053]

A semiconductor substrate fabrication method according to the present invention is characterized by comprising the step of forming an unporous layer on a porous layer formed on a surface of a first substrate, 10 the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich the unporous layer between the first substrate side and the second substrate, the removal step of removing the first substrate from the 15 adhered structure to expose the porous layer on a second substrate side thereof, and the etching step of etching the porous layer while the second substrate side on which the porous layer is exposed is completely dipped into an etching solution, and ultrasonic waves are 20 supplied, thereby exposing a surface of the second substrate side, the etching step swinging the second substrate side.

[0054]

A semiconductor substrate fabrication method 25 according to the present invention is characterized by comprising the step of forming an unporous layer on a

porous layer formed on a surface of a first substrate,
the step of adhering a first substrate side of a
prospective structure and a second substrate prepared
separately to sandwich the unporous layer between the
5 first substrate side and the second substrate, the
removal step of removing the first substrate from the
adhered structure to expose the porous layer on a second
substrate side thereof, and the etching step of etching
the porous layer while the second substrate side on
10 which the porous layer is exposed is completely dipped
into an etching solution, and ultrasonic waves are
supplied, thereby exposing a surface of the second
substrate side, the etching step swinging the second
substrate side to cross a plane of vibration of
15 ultrasonic waves.

[0055]

A semiconductor substrate fabrication method
according to the present invention is characterized by
comprising the step of forming an unporous layer on a
20 porous layer formed on a surface of a first substrate,
the step of adhering a first substrate side of a
prospective structure and a second substrate prepared
separately to sandwich the unporous layer between the
first substrate side and the second substrate, the
25 removal step of removing the first substrate from the
adhered structure to expose the porous layer on a second

substrate side thereof, and the etching step of etching the porous layer while the second substrate side on which the porous layer is exposed is completely dipped into an etching solution and supported substantially
5 perpendicular to a plane of vibration of ultrasonic waves, and ultrasonic waves are supplied, thereby exposing a surface of the second substrate side, the etching step swinging the second substrate side to cross the plane of vibration of ultrasonic waves.

10 [0056]

A semiconductor substrate fabrication method according to the present invention is characterized by comprising the step of forming an unporous layer on a porous layer formed on a surface of a first substrate,
15 the step of adhering a first substrate side of a prospective structure and a second substrate prepared separately to sandwich the unporous layer between the first substrate side and the second substrate, the removal step of removing the first substrate from the
20 adhered structure to expose the porous layer on a second substrate side thereof, and the etching step of etching the porous layer while the second substrate side on which the porous layer is exposed is completely dipped into an etching solution and supported substantially
25 parallel to a plane of vibration of ultrasonic waves, and ultrasonic waves are supplied, thereby exposing a

surface of the second substrate side, the etching step swinging the second substrate side to cross the plane of vibration of ultrasonic waves.

[0057]

5 [Embodiments]

A preferred embodiment of the present invention will be described below with reference to the accompanying drawings.

[0058]

10 [First Embodiment]

Fig. 1A is a view showing an outline of the construction of a wafer processing apparatus according to the preferred embodiment of the present invention. The wafer processing apparatus according to this
15 embodiment can be widely applied to etching, cleaning, and another processing which supplies a processing solution to a wafer.

[0059]

In a wafer processing apparatus 100 according to
20 this embodiment, portions which may come into contact with a processing solution are preferably made from quartz or plastic in accordance with the intended use. Preferable examples of the plastic are a fluorine resin, vinyl chloride, polyethylene, polypropylene,
25 polybutyleneterephthalate (PBT), and polyetheretherketone (PEEK). Preferable examples of the

fluorine resin are PVDF, PFA, and PTFE.

[0060]

This wafer processing apparatus 100 has a wafer processing bath 11, and a holder driving mechanism 31
5 for swinging a wafer holder 21 in the wafer processing bath 11. The wafer processing apparatus 100 preferably comprises an ultrasonic bath 61.

[0061]

To process wafers, the wafer processing bath 11 is
10 filled with a processing solution. A 4-plane overflow bath 12 is mounted on the wafer processing bath 11, and supplies a processing solution from the bottom portion of the wafer processing bath 11 into the wafer processing bath 11 by a circulator 71 incorporating a
15 filter. The processing solution overflowing from the wafer processing bath 11 is stored in the 4-plane overflow bath 12, and discharged from the bottom portion of the 4-plane overflow bath 12 toward the circulator 71. Since the wafer processing apparatus 100 agitates the
20 processing solution while swinging the wafer holder 21 by the holder driving mechanism 31, the liquid level of the processing solution can be kept constant. Therefore, the circulating system including the 4-plane overflow bath 12 is very useful.

25 [0062]

The wafer holder 21 may be a commercially available

product, and is preferably made from quartz or plastic. Preferable examples of the plastic are a fluorine resin, vinyl chloride, polyethylene, polypropylene, polybutyleneterephthalate (PBT), and

5 polyetheretherketone (PEEK). Preferable examples of the fluorine resin are PVDF, PFA, and PTFE.

[0063]

The holder driving mechanism 31 has a pair of gripping portions 31a for gripping the wafer holder 21. 10 The wafer holder 21 is gripped by the pair of gripping portions 31a and dipped in the wafer processing bath 11. While the wafer holder 21 is swung within the wafer processing bath 11, desired processing can be performed for a wafer 41. The holder driving mechanism 31 15 functions to convey the wafer holder 21 holding the wafer 41 having undergone previous processing to the wafer processing bath 11 or the next processing, whereas it functions as part of the wafer processing apparatus 100.

20 [0064]

In this embodiment, the wafer 41 is indirectly held by holding the wafer holder 21 with the gripping portions 31a. Alternatively, the wafer 41 can be directly held by, e.g., a chucking pad in place of the 25 gripping portions 31a. The direction to hold the wafer 41 is not limited to a direction perpendicular to the

bottom surface of the wafer processing bath 11, and may be a direction parallel to the bottom surface.

[0065]

A swing support member 13 for increasing the swing efficiency of the wafer 41 in swinging the wafer 41 by the holder driving mechanism 31 is preferably arranged at the bottom portion of the wafer processing bath 11. When the wafer holder 21 moves, the swing support member 13 contacts the peripheral portion of the wafer 41 held by the wafer holder 21 to rotate the wafer 41 by the frictional force and vertically move it within the wafer holder 21. The swing support member 13 is useful for improving the in-plane uniformity of the processed wafer.

[0066]

It is also effective to arrange a driving mechanism for moving the swing support member 13 vertically (y-axis direction) and/or horizontally (x-axis direction). In this case, the swing support member 13 itself can move to rotate the wafer 41 and vertically move it within the wafer holder 21. Accordingly, the moving range of the wafer holder 21 by the holder driving mechanism 31 can be reduced, and in other words, the wafer processing bath 11 can be downsized.

[0067]

An ultrasonic source 51 is arranged in the ultrasonic bath 61, and filled with an ultrasonic

transmitting medium (e.g., water). The ultrasonic source 51 is fixed to an adjusting mechanism 62 for vertically and/or horizontally adjusting the position of the ultrasonic source 51. Ultrasonic waves to be supplied to the wafer processing bath 11, more specifically, to the wafer 41 can be optimized by adjusting the positional relationship between the ultrasonic source 51 and the wafer processing bath 11 by the adjusting mechanism 62. The ultrasonic source 51 preferably has a function of adjusting the frequency or strength of ultrasonic waves to be generated. This can further optimize the supply of ultrasonic waves. Since the ultrasonic source 51 has the function for optimizing the supply of ultrasonic waves to the wafer 41, various types of wafers can be processed.

[0068]

Fig. 1B is a view showing an outline of the construction of the holder driving mechanism 31. The gripping portions 31a are opened by extending opening/closing rods 31b, and closed by contracting these rods 31b. The holder driving mechanism 31 moves in the x-axis direction along a horizontal driving shaft 31c and in the y-axis direction along a vertical driving shaft 31d.

[0069]

Figs. 2A to 2E are views for explaining a wafer

swinging method. In Figs. 2A to 2E, the arrows indicate the moving direction of the wafer holder 21. Fig. 2A shows a state immediately before starting swinging a wafer. When the start of wafer swinging is instructed, 5 the holder driving mechanism 31 depresses the gripping portions 31a downward under computer control, as shown in Fig. 2B. During this depression, the peripheral portion of the wafer 41 comes into contact with the swing support member 13. As a result, the lower portion 10 of the wafer 41 is supported by the swing support member 13.

[0070]

The swing support member 13 may generate a few particles upon contact with the wafer 41. The swing 15 support member 13 preferably smoothly contacts the wafer 41 by rounding the distal end portion of the swing support member 13, as shown in Fig. 3.

[0071]

Since the swing support member 13 suffices to 20 support the swing of the wafer 41, it can be formed into a shape, e.g., a thin plate not to obstruct the transmission of ultrasonic waves. With this shape, the ultrasonic waves to be supplied to the wafer 41 can be uniformed to uniformly process the wafer 41.

25 [0072]

Slight ultrasonic nonuniformity caused by the swing

support member 13 does not pose any problem because the wafer processing apparatus 100 processes the wafer 41 while changing the relative positional relationship between the wafer 41 and the swing support member 13, in
5 other words, the relative positional relationship between the wafer 41 and the wafer processing bath 11.
[0073]

Since a slightly larger depression amount of the wafer holder 21 can increase the contact pressure
10 between the wafer 41 and the swing support member 13, a slip between the swing support member 13 and the wafer 41 can be prevented to prevent operation failure. This is because, if the depression amount is too small, the gravity for the wafer 41 acts on the wafer holder 21
15 more greatly than on the distal end portion of the swing support member 13. When the swing support member 13 having the shape according to this embodiment is used, the depression amount is preferably about 30 mm after the wafer 41 comes into contact with the swing support
20 member 13.
[0074]

Upon depressing the wafer holder 21, the holder driving mechanism 31 moves the gripping portions 31a rightward (positive direction of the X axis) under
25 computer control, as shown in Fig. 2C. As a result, the wafer 41 substantially horizontally moves rightward

(positive direction of the X axis) in the wafer processing bath 11 while rotating clockwise. The moving amount of the gripping portions 31a must be set to fall within the range in which these gripping portions 31a do not collide against an opening portion at the lower portion of the wafer holder 21.

[0075]

After the wafer holder 21 has moved rightward (positive direction of the X axis), the holder driving mechanism 31 vertically moves the gripping portions 31a under computer control, as shown in Fig. 2D. The moving amount of the gripping portions 31a preferably falls within the range in which the wafer 41 does not come close to a liquid surface 14 of the processing solution. This is because particles may attach to the surface of the wafer 41 if the wafer 41 comes close to the liquid surface 14.

[0076]

Upon completion of the upward movement of the wafer holder 21, the holder driving mechanism 31 moves the gripping portions 31a leftward (negative direction of the X axis) under computer control to return them in the initial state (Fig. 2A), as shown in Fig. 2E.

[0077]

By repeatedly performing the above operation (Fig. 2A → Fig. 2B → Fig. 2C → Fig. 2D → Fig. 2E), the wafer

41 can be properly swung and uniformly processed.

[0078]

According to the wafer processing apparatus 100,
since the wafer 41 is swung in the region where the
5 supply of ultrasonic waves is optimized by adjusting the
ultrasonic bath 61, ultrasonic waves which act on the
wafer 41 can be optimized.

[0079]

The standing waves of ultrasonic waves have loops
10 (low-strength portions) and nodes (high-strength
portions) at constant separation. Therefore, ultrasonic
waves are difficult to uniform in the wafer processing
bath 11.

[0080]

15 However, since the wafer processing apparatus 100
swings the wafer 41 with the holder driving mechanism 31,
it can uniformly process the wafer 41 regardless of a
somewhat nonuniform distribution of the ultrasonic wave
strength. Even if the direction to move the wafer 41 is
20 a simple direction such as only the horizontal, vertical,
or oblique direction, it can contribute to the
processing uniformity of the wafer 41. By swinging the
wafer 41 in its axial direction (z-axis direction), the
processing nonuniformity between wafers attributed to
25 high-strength portions of ultrasonic waves in the
horizontal plane can be corrected.

[0081]

Since the wafer processing apparatus 100 further comprises the swing support member 13, the swinging amount of the wafer 41 can be efficiently increased. The
5 fixed position of the swing support member 13 is not limited to the bottom portion of the wafer processing bath 11. As far as the swing support member 13 can contact with all wafers 41 of the wafer holder 21, it can be fixed to, e.g., the side wall of the wafer
10 processing bath 11 or the holder driving mechanism 31 (in this case, a mechanism of changing the relative positional relationship between the swing support member 13 and the gripping portions 31a is arranged).

[0082]

15 According to the wafer processing apparatus 100, since no driving mechanism exists in the wafer processing bath 11, no particle is produced by the driving mechanism.

[0083]

20 Even if the wafer processing apparatus 100 does not comprise any ultrasonic bath 61, it can function as an apparatus suitable for wafer processing. More specifically, if the wafer processing apparatus 100 has a function of swinging the wafer holder 21 within the
25 wafer processing bath 11 by the holder driving mechanism 31, it can uniformly process the wafer 41 with only this

function, and effectively agitate the processing solution. A gas or the like produced upon processing the wafer 41 can be efficiently removed from the surface of the wafer 41. Since the holder driving mechanism 31 can
5 serve as both convey and swinging mechanisms for the wafer 41, wafers can be efficiently processed.

[0084]

Fig. 4 is view of another example of the construction of the swing support member 13. Fig. 4(a)
10 is an overall view and Fig. 4(b) is an enlarged view of part of the swing support member 13. If the strength of ultrasonic waves is high, the distal end portion of the swing support member 13 and the wafer 41 may slip and fail to efficiently swing the wafer 41.

15 [0085]

A swing support member 13' shown in Figs. 4 has V-shaped grooves 13a at constant intervals. By forming these V-shaped grooves 13a, the contact area with the wafers 41 can be increased. Since the swing support
20 member 13' engages with the wafer 41 so as to pinch it, the swing efficiency of the wafer 41 increases. Even if the wafer 41 vibrates to be temporarily spaced apart from the swing support member 13', the frictional force with the wafer 41 does not decrease unless the wafer 41
25 accurately vertically moves.

[0086]

The groove at the distal end portion of the swing support member 13' may have a shape 13b, i.e., a full-wave rectifying shape. In this case, since the groove does not have any top, unlike the V-shaped groove 13a, generation of particles upon contact with the wafer 41 can be suppressed.

[0087]

[Second Embodiment]

Fig. 5A is a perspective view showing an outline of the construction of a wafer processing system incorporating a wafer processing apparatus 100. Fig. 5B is a front view showing part of the wafer processing system shown in Fig. 5A.

[0088]

This wafer processing system is preferably a combination of a loader, a wafer processing apparatus (e.g., an etching or cleaning apparatus), a spin dryer, an unloader, and the like.

[0089]

Reference numeral 31' denotes a holder driving mechanism having substantially the same function as that of the holder driving mechanism 31, which has gripping portions 31a' for gripping a wafer holder 21, a means for driving the wafer holder 21 horizontally (alignment direction of the respective apparatuses), and a means for vertically driving the wafer holder 21.

[0090]

This wafer processing system can automatically process a wafer under computer control. Particles produced by the intervention of the operator can be
5 prevented from attaching to wafers, and the processing efficiency can be increased.

[0091]

[Third Embodiment]

The third embodiment will exemplify another wafer
10 swinging method. Figs. 6A to 6D are views for explaining a wafer swinging method in this embodiment. In Figs. 6A to 6D, the arrows indicate the moving direction of a wafer holder 21. Fig. 6A shows a state immediately before starting swinging a wafer. When the start of
15 wafer swinging is instructed, a holder driving mechanism 31 moves gripping portions 31a downwardly to the right under computer control, as shown in Fig. 6B. The moving direction is suitably at an angle of about 45° with respect to the horizontal plane. When the wafer holder
20 21 has moved downwardly to the right, a wafer 41 rotates clockwise about the distal end portion of a swing support member 13 while its peripheral portion is pressed by the left side wall of the wafer holder 21.

[0092]

25 After the wafer holder 21 has moved downwardly to the right, the center of gravity of the wafer 41 moves

to the right with respect to the distal end portion of the swing support member 13, and the wafer 41 rotates toward the right side wall of the wafer holder 21 to settle to a state shown in Fig. 6C.

5 [0093]

Upon moving the wafer holder 21 downwardly to the right, the holder driving mechanism 31 moves the gripping portions 31a upwardly to the left, as shown in Fig. 6D. The moving direction is preferably opposite to
10 the moving direction shown in Fig. 6B.

[0094]

When the wafer holder 21 has moved upwardly to the left, the wafer 41 rotates counterclockwise about the swing support member 13 while its peripheral portion is
15 pressed by the right side wall of the wafer holder 21. By moving the wafer holder 21 to a state shown in Fig. 6A, one operation is completed.

[0095]

By repeatedly performing the above operation (Fig.
20 6A → Fig. 6B → Fig. 6C → Fig. 6D), the wafer 41 can be properly swung and uniformly processed.

[0096]

[Fourth Embodiment]

The fourth embodiment is directed to a wafer
25 processing apparatus having another construction. Fig. 7 is a view showing an outline of the construction of the

wafer processing apparatus according to this embodiment.
The same reference numerals as in the construction of
the wafer processing apparatus 100 according to the
first embodiment denote substantially the same
5 constituent elements, and a description thereof will be
omitted.

[0097]

A wafer processing apparatus 101 according to the
fourth embodiment holds a wafer 41 with a wafer moving
10 mechanism 80 almost parallel to the bottom surface of a
wafer processing bath 11 (i.e., almost parallel to the
plane of vibration of ultrasonic waves), and swings the
wafer 41 while completely dipping it into a processing
solution (e.g., cleaning or etching solution) within the
15 wafer processing bath 11. In this manner, the wafer 41
is uniformly processed, and contamination of the wafer
41 by particles is prevented.

[0098]

The wafer moving mechanism 80 grips the wafer 41
20 with arms 81, and swings the wafer 41 in the wafer
processing bath 11. The wafer 41 is preferably swung in
a direction perpendicular to the plane of vibration of
ultrasonic waves (i.e., vertical direction), or in a
direction parallel to the plane of vibration (i.e.,
25 horizontal direction).

[0099]

Also in the wafer processing apparatus 101, the wafer 41 is preferably processed while being completely dipped into the processing solution. In this case, particles can be prevented from attaching to the wafer
5 41 near the interface between the processing solution and ambient atmosphere.

[0100]

According to the wafer processing apparatus 101, the wafer 41 can be uniformly processed by swinging it
10 in the wafer processing bath 11.

[0101]

[Application of Wafer Processing Apparatus]

The wafer processing apparatus 100 according to the above embodiments is suitable as, e.g., an etching
15 apparatus. According to this etching apparatus, 1) a wafer can be uniformly etched, 2) contamination by particles can be reduced, and 3) the etching rate can be increased.

[0102]

20 The wafer processing apparatus 100 is suited as an etching apparatus for etching a wafer having a porous silicon layer. The mechanism of etching of porous silicon is disclosed in K. Sakaguchi et al., Jpn. Appl. Phys. Vol. 34, part 1, No. 2B, 842 - 847 (1995). Porous
25 silicon is etched when an etching solution penetrates into the pores of porous silicon by a capillary action

and etches the walls of the pores. As the walls of the pores become thinner, these walls cannot support themselves beyond some point. Finally, the porous layer entirely collapses to complete the etching. When the pore walls are left to collapse by the action of only the etching solution without any etching assistance, the etching rate of the hole wall is low, and the etching time is long. In a region where the porous layer collapses, the underlayer is etched. For this reason, variations in in-plane etching rate of a porous silicon wafer and etching rate between wafers are preferably suppressed as much as possible.

[0103]

For example, a first substrate is prepared by forming a porous silicon layer on a single-crystal silicon substrate, growing an epitaxial layer on the porous silicon layer, and forming an insulating film on the epitaxial layer. The first substrate and a second substrate are so adhered as to sandwich the insulating film between them. Then, the single-crystal silicon substrate is removed from the lower surface of the first substrate, and the porous silicon layer is etched to fabricate an SOI wafer. This method requires an etching selectivity (porous silicon/epitaxial layer) of only about 10^5 .

[0104]

Even if an etching method having high selectivity is employed, however, the surface of the SOI layer exposed upon removing the porous silicon layer by etching is slightly etched. Such slight unwanted etching
5 does not seriously degrade the thickness uniformity of the SOI layer, but higher selectivity and higher thickness uniformity are demanded. In the future, as the wafer size increases, higher thickness uniformity of the SOI layer will be demanded.

10 [0105]

When the wafer processing apparatus 100 is applied to a porous silicon etching apparatus, in-plane variations of the SOI layer and variations between wafers can be suppressed by swinging wafers within the
15 wafer processing bath, and higher-quality SOI substrates can be fabricated.

[0106]

By swinging wafers, and in addition, performing etching while supplying ultrasonic waves, the collapse
20 of the porous silicon layer can be promoted, the etching time can be shortened, and the etching selectivity can be increased.

[0107]

An example of a method of fabricating a
25 semiconductor substrate using the wafer processing apparatus according to the above embodiments will be

described below.

[0108]

Fig. 8 a is view showing the method of fabricating a semiconductor substrate. Roughly speaking, in this fabrication method, the first substrate is prepared by forming a porous silicon layer on a single-crystal silicon substrate, forming an unporous layer on the porous silicon layer, and preferably forming an insulating film on the unporous layer. The first structure and a second substrate prepared separately are so adhered as to sandwich the insulating film between them. After that, the single-crystal silicon substrate is removed from the lower surface of the first substrate, and the porous silicon layer is etched to fabricate a semiconductor substrate.

[0109]

The method of fabricating a semiconductor substrate will be described in detail below with reference to Fig. 8.

[0110]

A single-crystal Si substrate 501 for forming the first substrate is prepared, and a porous Si layer 502 is formed on the major surface of the single-crystal Si substrate 501 (see Fig. 8A). At least one unporous layer 503 is formed on the porous Si layer 502 (see Fig. 8B). Preferable examples of the unporous layer 503 are a

single-crystal Si layer, a poly-Si layer, an amorphous Si layer, a metal film layer, a compound semiconductor layer, and a superconductor layer. An element such as MOSFET may be formed on the unporous layer 503.

5 [0111]

An SiO₂ layer 504 is preferably formed as another unporous layer on the unporous layer 503, and used as the first substrate (see Fig. 8C). The SiO₂ layer 504 is useful because, when the first substrate and a second
10 substrate 505 are adhered in the subsequent step, the interface energy at the adhered interface can be removed from an active layer.

[0112]

The first substrate and the second substrate 505
15 are tightly adhered at room temperature so as to sandwich the SiO₂ layer 504 between them (see Fig. 8D). This adhesion may be strengthened by performing anode coupling, pressurization, or heat treatment, as needed, or a combination of them.

20 [0113]

When a single-crystal Si layer is formed as the unporous layer 503, the first substrate is preferably adhered to the second substrate 505 after the SiO₂ layer 504 is formed on the surface of the single-crystal Si
25 layer by thermal oxidization or the like.

[0114]

Preferable examples of the second substrate 505 are an Si substrate, a substrate having an SiO₂ layer formed on an Si substrate, a light-transmitting substrate such as a quartz substrate or the like, and a sapphire
5 substrate. The second substrate 505 suffices to have a flat surface to be adhered, and may be another type of substrate.

[0115]

Fig. 8D shows the adhered state of the first and
10 second substrates via the SiO₂ layer 504. The SiO₂ layer 504 need not be formed when the unporous layer 503 or the second substrate is not Si.

[0116]

In adhesion, a thin insulating plate may be
15 inserted between the first and second substrates.

[0117]

The first substrate is removed from the second substrate at the boundary of the porous Si layer 502 (see Fig. 8E). The removal method includes the first
20 method (of discarding the first substrate) using grinding, polishing, etching, or the like, and the second method of separating the first and second substrates at the boundary of the porous layer 502. In the second method, the first substrate can be recycled
25 by removing porous Si left on the separated first substrate, and planarizing the surface of the first

substrate, as needed.

[0118]

The porous Si layer 502 is selectively etched and removed (see Fig. 8F). The wafer processing apparatus 5 100 or 101 is suitable for this etching. Since this wafer processing apparatus supplies ultrasonic waves while completely dipping a wafer (in this case, the wafer shown in Fig. 8E) into an etching solution and swinging it, the wafer is hardly contaminated by 10 particles, and the etching is made uniform. According to this wafer processing apparatus, the etching time is shortened, and the etching selectivity between the unporous layer 503 and the porous layer 504 increases. The etching time is shortened because etching is 15 promoted by ultrasonic waves, and the etching selectivity increases because the promotion of etching by ultrasonic waves is more remarkable on the porous layer 504 than on the unporous layer 503.

[0119]

20 When the unporous layer 503 is single-crystal Si, the following etching solutions are suited in addition to a general etching solution for Si.

[0120]

- (a) hydrofluoric acid
- 25 (b) solution mixture prepared by adding at least one of alcohol and hydrogen peroxide to hydrofluoric

acid

(c) buffered hydrofluoric acid

(d) solution mixture prepared by adding at least one of alcohol and hydrogen peroxide to buffered

5 hydrofluoric acid

(e) solution mixture of hydrofluoric acid, nitric acid, and acetic acid

Using these etching solutions, the porous layer 502 can be selectively etched to leave the underlying
10 unporous layer 503 (single-crystal Si). The porous layer 502 is readily selectively etched by these etching solutions because porous Si has an enormous surface area and hence etching progresses at a very high speed for the unporous Si layer.

15 [0121]

Fig. 8E schematically shows a semiconductor substrate obtained by the above fabrication method. According to this fabrication method, the flat unporous layer 503 (e.g., single-crystal Si layer) is uniformly
20 formed on the entire surface of the second substrate 505.

[0122]

For example, if an insulating substrate is employed as the second substrate 505, the semiconductor substrate obtained by the above fabrication method is effectively
25 used to form insulated electronic elements.

[0123]

[Effect of the Invention]

The present invention can make wafer processing uniform, and can prevent contamination of a wafer caused by particles.

[Type of the Document] Abstract

[Abstract]

[Problem] To make wafer processing uniform.

[Solving Means] A holder driving mechanism holds a wafer
5 holder with gripping portions, and swings it within a
wafer processing bath. When the peripheral portion of a
wafer comes into contact with the distal end portion of
a swing support member, the wafer rotates and vertically
moves in the wafer holder. The wafer can be efficiently
10 swung, and processing can be made uniform. By supplying
ultrasonic waves from an ultrasonic bath, the processing
rate can be increased.
